The following list shows how u-blox implements the NMEA protocol, and the conditions determining how flags are set in version 2.2 and below.

NMEA Message: Field	No position fix (at power-up, after losing satellite lock)	Valid position fix with GPS, but user limits exceeded	Valid dead reckoning fix, but user limits exceeded	Dead reckoning (linear extrapolation, ADR with external sensors, or map matching)	2D position fix	3D position fix	combined GPS/SFDR position fix (ADR with external sensors)

By default the receiver will not output invalid data. In such cases, it will output empty fields.

- A valid position fix is reported as follows:

\$GPGLL,4717.11634,N,00833.91297,E,124923.00,A,A*6E

- An invalid position fix (but time valid) is reported as

follows: \$GPGLL,,,,,124924.00,V,N*42

- If Time is unknown (e.g. during a cold-start): \$GPGLL,,,,,V,N*64

An exception from the above default are dead reckoning fixes, which are also output when invalid (user limits exceeded).

In Antaris firmware versions older than 3.0, the receiver did output invalid data and marked it with the 'Invalid/Valid' Flags. If required, this function can still be enabled in later firmware versions, using the UBX protocol message [CFG-NMEA](#).

Differing from the NMEA standard, u-blox reports valid dead reckoning fixes with user limits met (not exceeded) as valid (A) instead of invalid (V).

<i>Message</i>	GBS		
<i>Description</i>	GNSS Satellite Fault Detection		
<i>Firmware</i>	Supported on u-blox 6 from firmware version 6.00 up to version 7.03.		
<i>Type</i>	Output Message		
<i>Comment</i>	<p>This message outputs the results of the Receiver Autonomous Integrity Monitoring Algorithm (RAIM).</p> <ul style="list-style-type: none"> The fields errlat, errlon and erralt output the standard deviation of the position calculation, using all satellites which pass the RAIM test successfully. The fields errlat, errlon and erralt are only output if the RAIM process passed successfully (i.e. no or successful Edits happened). These fields are never output if 4 or fewer satellites are used for the navigation calculation (because - in this case - integrity can not be determined by the receiver autonomously) The fields prob, bias and stddev are only output if at least one satellite failed in the RAIM test. If more than one satellites fail the RAIM test, only the information for the worst satellite is output in this message.

Layout Rules

Do not routing the other signal or power trace under the engine board .

* RF:

This pin receives signal of GPS analog via external active antenna .It has to be a controlled impedance trace at 50ohm.

Do not place the RF traces close to the other signal path and not routing it on the top layer.

Keep the RF traces as short as possible.

* Antenna:

Keep the active antenna on the top of your system and confirm the antenna radiation pattern 、 axial ratio power gain noise figure VSWR are correct when you Setup the antenna in your case.

GPS Passive (or Active) Antenna Specifications(Recommendation)

Frequency: 1575.42 ± MHz

Axial Ratio: 3 dB Typical

Output Impedance: 50Ω

Polarization: RHCP

Output VSWR: 1.5 Max.

Active option

Low Noise Amplifier:

Amplifier Gain :16~20dB Typical

Output VSWR: 2.0 Max.

Noise Figure: 2.0 dB Max.

Antenna Input Voltage :3.3V Typical

Design Notes

VCC

This is the main power supply to the engine board. (3.3Vdc ±5%),VCC Ripple less than 50Mv.

GND

Ground pin for the baseband circuit.

RXD

This is the main channel for receiving software commands from u-blox software or from your proprietary software.

TXD

This is the main transmits channel for outputting navigation and measurement data to user's navigation software or user written software. Output TTL level, 0V ~ 2.85V

RF_IN

This pin receives signal of GPS analog via external active antenna . It has to be a controlled impedance trace at 50ohm. Do not have RF traces closed the other signal path and routing it on the top layer.

Keep the RF traces as short as possible.

VBCK

This is the battery backup power input for the SRAM and RTC when main power is removed. Typical, the current draw is 15uA. Without the external backup battery, the module/engine board will always execute a cold start after turning on. To achieve the faster start-up offered by a hot or warm start, a battery backup must be connected. The battery voltage should be between 1.8v and 3.6v.

1PPS

1 pulse per second synchronized at rising edge pulse length 100ms.

INT

This pin will used in future functions in low-power modes.
